Coverage Planning

Coverage Planning

In order to carry out the tasks within the scope of the strategic radio network planning and the radio coverage planning, respectively, the following is required:

- Radio propagation models
Prediction of the mean path loss between BS and MS (see previous files)
- Models for the description of the fading effects
Calculation of the coverage probability
- Information about system technology regarding BS and MS
set-up of the link budget

With this information, it is possible

- to estimate the number of required base stations from a given coverage probability for an area to be planned and from the information about the system technology and
- to calculate the radio coverage for a given base station and for a full network or a subnetwork, respectively.

Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/3/38

Institut für Nachrichtentechnik

Coverage Probability

- Using a radio propagation model, only the mean path loss can be predicted.
- The mean path loss is superposed by fading effects owing to
 - local shadowing effects (long-term fading) not considered by the model
 - multipath propagation (short-term fading)
- The influence of the short-term fading phenomena is normally eliminated through averaging by the receivers in the BS and the MS, respectively (especially using GSM).

Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/5/38

Institut für Nachrichtentechnik

Calculation of the Coverage Probability

- Description of the variations due to long-term fading by lognormal fading, i.e. the logarithmised receive level x in dBm is normal-distributed with a mean value x_m and a standard deviation σ
- Probability density function:

$$p(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-x_m)^2}{2\sigma^2}}$$

- Probability that a level x_0 is exceeded (coverage probability):

$$P[x \geq x_0] = \int_{x_0}^{\infty} p(x) dx = \int_{x_0}^{\infty} \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-x_m)^2}{2\sigma^2}} dx = \frac{1}{2} - \frac{1}{2} \operatorname{erf}\left(\frac{x_0 - x_m}{\sigma\sqrt{2}}\right)$$

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/6/38

Institut für Nachrichtentechnik

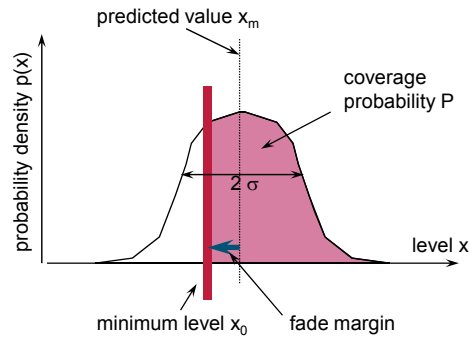

Calculation of the Coverage Probability

- In practice, x_0 corresponds to the receiver sensitivity (measured minimum level at which reception is possible).

- Fade margin: difference between the predicted value x_m and the minimum level x_0

- Example:

- $x_0 = -100$ dBm
- $x_m = -95$ dBm
- $\sigma = 7.4$ dB
- $P = 75\%$

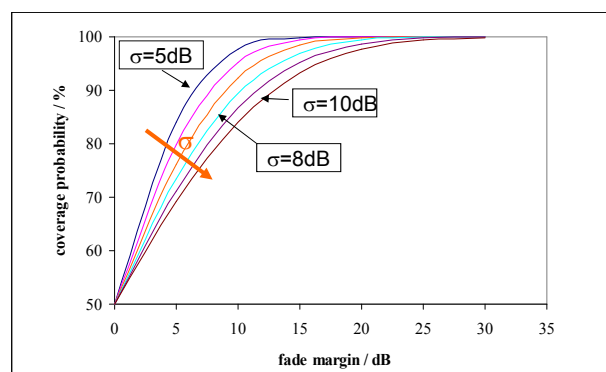

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/7/38

Calculation of the Coverage Probability

- Dependence of the coverage probability on the fade margin and the standard deviation

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/8/38

Calculation of the Coverage Probability

- $P_{x_0}[x > x_0]$ corresponds to the coverage probability at a single reception point.
- In general, the lowest receive levels are obtained for the reception points located on the cell boundary.
- Therefore, a planning guideline often applied is to achieve a minimum coverage probability on the cell boundary.
- For all other reception points of the cell, lower path losses and thus higher coverage probabilities arise.
- Proportion of the reception points with a measured signal larger than x_0 :

$$p_{\text{Zelle}} = \frac{1}{\text{Zellfläche}} \iint_{\text{Zellfläche}} P_{x_0}(x > x_0) dA$$

- p_{Zelle} is also referred to as area coverage probability.

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/9/38

Institut für Nachrichtentechnik

Calculation of the Coverage Probability

- The integral in the previous equation depends on the local distribution of the path losses. In general, it can only be solved numerically.
- Analytical solution assuming a circular cell area and a very simplified propagation model:

$$x(r) = \alpha - 10n \log \frac{r}{r_{\max}}$$

$$p_{\text{Zelle}} = \frac{1}{\pi r_{\max}^2} \int_0^{r_{\max}} P_{x_0}[x(r) > x_0] 2\pi r dr$$

$$p_{\text{Zelle}} = \frac{1}{2} \left[1 - \text{erf}(a) + e^{\frac{1-2ab}{b^2}} \left(1 - \text{erf}\left(\frac{1-ab}{b}\right) \right) \right]$$

$$a = \frac{x_0 - \alpha}{\sigma\sqrt{2}} \quad (3-7) \quad b = \frac{\sigma\sqrt{2}}{10n \log e}$$

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017/10/38

Institut für Nachrichtentechnik

Special Case

- $x_m = x_0$ for $r = r_{\max} \rightarrow \alpha = x_0 \rightarrow a = 0$
- This case complies with a coverage probability of 50 % on the cell boundary.
- Equation for the calculation of the area coverage probability is reduced to:

$$p_{\text{Zelle}} = \frac{1}{2} \left[1 - e^{\frac{1}{b^2}} \left(1 - \operatorname{erf} \left(\frac{1}{b} \right) \right) \right]$$

- The area coverage probability only depends on the ratio σ/n .
- Example: For $n = 3$ and $\sigma = 9$ dB, $p_{\text{Zelle}} = 71$ % is obtained.

Technische
Universität
Braunschweig

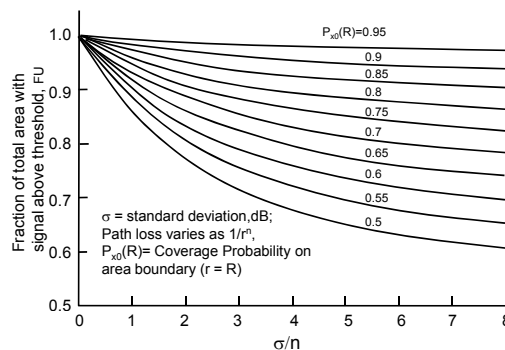

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|11/38

Institut für Nachrichtentechnik

Calculation of the Coverage Probability

- Relation between the coverage probabilities on the cell boundary and inside the cell:

- Example: $x_0 = -100$ dBm; $x_m = -95$ dBm; $\sigma = 7.4$ dB; $P_{x_0} = 75$ %; $n = 3.8$
 $\rightarrow p_{\text{Zelle}} \approx 91$ %

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|12/38

Institut für Nachrichtentechnik

Link Budget

- Maximum allowed transmission loss:
 - The cell size depends on the attenuation of the signal that may occur during radio propagation, without falling below the required C/I ratio at the receiver even at maximum transmitting power. The maximum allowed propagation loss is also called link budget.
 - General equation for the maximum allowed propagation loss:

$$L_F \leq L_{F \max} = \frac{P_S}{dBm} - \frac{P_{E \min}}{dBm} + \frac{G_R}{dBi} + \frac{G_T}{dBi} + \frac{\text{other gains}}{dB} - \frac{\text{other losses}}{dB} - \frac{\text{margins}}{dB}$$

- P_S transmitting power in dBm
- $P_{E \min}$ minimum received power
- G_R gain of the receive antenna
- G_T gain of the transmit antenna

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|13/38

Institut für Nachrichtentechnik

Link Budget

- Especially, characteristics of the base station and the mobile station have an influence on the link budget, including
 - maximum level of the output power of the BS
 - characteristics of the BS antenna (antenna diagram, gain, installation height etc.)
 - cable losses between the transmission power amplifier of the BS and the antenna
 - diversity gains
 - maximum level of the output power of the MS
 - gain of the MS antenna (assumption: mostly 0 dBi)
 - receiver sensitivity

Institut für Nachrichtentechnik

Cell Coverage

- In order to estimate the coverage of a cell, a simplified propagation model is assumed:
 - Example: Okumura Hata and Hata, respectively
 - Propagation in urban areas ("suburban", $D = 0$ in eq. (2-46))
 - BS antenna height: 25 m
 - MS antenna height: 1.5 m

→ distance dependence of the propagation loss:

- 900 MHz:
$$L(r) = 128.8 + 35.7 \log(r / km)$$

- 1800 MHz:
$$L(r) = 137.3 + 35.7 \log(r / km)$$

Universität
Braunschweig

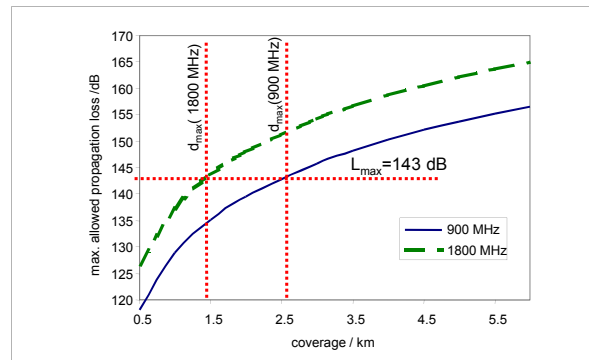

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|16/38

Institut für Nachrichtentechnik

Cell Coverage

- Reletion between the coverage and the maximum allowed propagation loss

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|17/38

Cell Coverage

- Calculation of the cell area regarding hexagonal networks:

- Hexagonal area (coverage area of a BS):

$$A_h = \frac{3\sqrt{3}}{2} R^2$$

- Cell area in case of threefold sectorisation:

$$A_{\text{Sektor}} = \frac{\sqrt{3}}{2} R^2$$

- Number of base stations required to cover an area A:

$$n \approx 0.4 \frac{A}{R^2}$$

Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|18/38

Approach to Estimate the Number of Base Stations

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|19/38

Planning Example: GSM1800 Network for Hannover

- Assumptions:
 - Link budget for GSM1800 according to GSM03.30 incl. 3dB body loss
 - Standard deviation for long-term fading: 7 dB
 - Calculation for two scenarios in terms of the assumed coverage probability P on the cell boundary:

coverage probability P	70 %	95 %
fading margin	3,7 dB	11,5 dB
maximum propagation loss	145,3 dB	137,5 dB
cell radius	1,8 km	1,5 km

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|20/38

Planning Example by Means of Potential Sites

- Estimation of the number of BSs using the previous equations and not idealised propagation conditions

Coverage for P = 70 % (11 BSs)

Coverage for P = 95 % (17 BSs)

Distribution of the Coverage Probabilities Considering the Planning Example Hannover

planning guideline P = 70% (11 BSs)

planning guideline P = 95% (17 BSs)

- At some reception points, the propagation conditions are less favourable than assumed in the (idealised) simplified propagation model.
- In practice, in strategic radio network planning improved methods for the estimation of the number of BSs are applied to some extent (consideration of topography and land use).

Site Planning

- Precise site planning
 - Determination of search areas for the potential sites

- Acquisition of a suitable site inside a search area
- Result of the acquisition: several possible sites (location candidates) if applicable

Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|23/38

Examples of Sites for Mobile Radio Antennas

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|24/38

Testing of Location Candidates

- Testing of the location candidates in terms of
 - their suitability for radio communication
 - Examination of the covered area by means of a prediction
 - Performance of a CW measurement if applicable

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|25/38

Testing of Location Candidates

- Space for system technology and antennas
- Possibilities to connect the BS with the BSC (radio relay, leased circuit)
 - regarding radio relay, additional test for LOS
- Application for permissions (building permit, EMCE certificate)

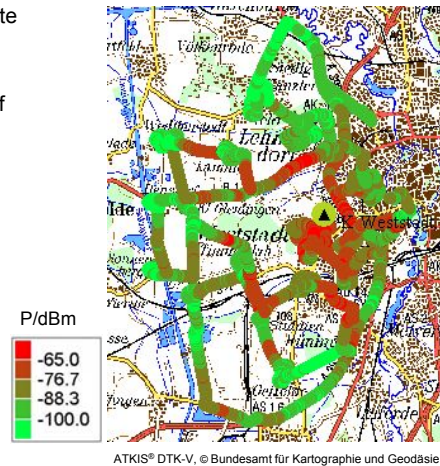

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|26/38

Example of a CW Test Run

- Result of a CW test run for a potential site in Braunschweig-Weststadt
 - frequency: 1800 MHz
 - omni-directional antenna with a gain of 11 dBi
 - antenna height: 38 m

Institut für Nachrichtentechnik

Planning in Detail

- Performance of the detailed planning:
 - Within the scope of site planning, the following parameters relevant for radio propagation have to be determined:
 - number of sectors
 - antenna type
 - antenna height
 - antenna orientation (azimuth and tilt)
 - tilt: electrical and mechanical, respectively
 - radiated power
 - number of TRXs

Planning Tools

Radio Network Planning Tools

- A radio network planning tool is the central tool for the most tasks to be carried out within the scope of radio network planning.
- In principle, such a radio network planning tool consists of three main components:
 - Graphical user interface for the input of data as well as for the visualisation of calculation results and stored data sets, respectively
 - Data base for the storage of all data
 - Radio network planning algorithms for the performance of the required calculations

Categorisation of Data

- Spatial data
 - Raster or vector data that can only be visualised using a geographic surface (all maps, but also calculation results)
 - Large amounts of data (→ versioning is difficult!)
- Non-spatial (alphanumeric) data
 - Data that can also be described alphanumeric
- Basic data
 - Data that are not modified in the planning process, e.g. antenna diagrams as well as geographic background data
- Site data
 - Site data (antenna data, co-ordinates, antenna height etc.)

Technische
Universität
Braunschweig

Coverage Planning | Prof. Dr.-Ing. Thomas Kürner | ESoA Course Large Scale Propagation | June 2017|37/38

Institut für Nachrichtentechnik

Categorisation of Data

- Spatial calculation results
 - e.g. predictions, cell presentations
- Cell-related planning parameters (planning status)
 - BSS parameters (frequencies, CI, LAC, RAC, handover parameters etc.)
- Operational data
 - Structure is identical to cell-related parameters
 - Status of data used in the operational network
 - Modifications in terms of the planning status, e.g. by manual network optimisations
- Measurement data
 - Large amounts of data where required
 - Spatial data sets (e.g. test runs based on coverage measurements)
 - Alphanumeric data (e.g. measurement data from OMC)
